(57) A tyre comprises a tread portion (2) in which a mould parting line by a single-split mould runs on or near the tyre equator (CO). In a central part (2C) of the tread portion in which tread grooves (4) are provided, the groove edges which are stroked by tyre mould's protrusions for making the tread grooves (4) when the mould is opened are provided with a chamfer backed by a recess and/or the groove walls extending from such groove edges are provided with a variable inclination, whereby demoulding defects can be reduced.

Fig.4

EP 1 106 395 A2

Description

[0001] The present invention relates to a tyre more particularly to a tread groove structure being capable of reducing demoulding defects caused by a single-split mould.

[0002] In comparison with a segmental mould which comprises circumferentially divided, radially movable sectors, a single-split mould or two-piece mould having a split face on or near the tyre equator is known as low cost because the mould itself and incidental equipment, controller and the like are simple.

[0003] When such a single-split mould is opened to take out the vulcanised tyre therefrom, as the two mould pieces are moved apart in the tyre axial direction, grooved parts in the tread portion of the tyre are liable to be damaged by protrusions which are provided on the inside of the mould in order to make tread grooves. Demoulding defects are more liable to occur as the inclination angle of the groove becomes smaller with respect to the tyre circumferential direction and in the tread central portion than the tread shoulder portion.

[0004] On the other hand, ordinary pneumatic tyres are provided in the tread portion with a circumferential groove and/or a less-inclined oblique groove. Accordingly, it is difficult to manufacture such tyres using a single-split mould although it can reduce the tyre production cost.

[0005] It is therefore, an object of the present invention to provide a pneumatic tyre which can be made without demoulding defects using a single-split mould even if a circumferential groove and/or less-inclined oblique grooves are disposed in the tread central portion.

[0006] According to the present invention, a tyre comprises a tread portion in which a mould parting line by a single-split mould runs on or near the tyre equator defining a right-hand part of the tread portion on one side of the mould parting line and a left-hand part on the other side, the tread portion provided in at least a central part with tread grooves each having a right-hand groove wall and a left-hand groove wall, wherein in the right-hand part, the right-hand groove walls are at least partially provided with an inclined part extending from the tread face towards the groove bottom while inclining to the left, and the left-hand groove walls are inclined less than the inclined part of the respective opposite right-hand groove walls, in the left-hand part, the left-hand groove walls are provided with an inclined part extending from the tread face towards the groove bottom while inclining to the right, and the right-hand groove walls are inclined less than the inclined part of the respective opposite left-hand groove walls, and the inclined parts are a first inclined part extending from the tread face to the vicinity of the groove bottom, while inclining at a first inclination angle of from 15 to 45 degrees, and/or a second inclined part inclined at a second inclination angle of from 30 to 60 degrees and having a width of from 0.3 to 2 mm when measured in parallel to the tread face and accompanied by a recess which is narrower and shallower than the tread groove and extends along the second inclined part.

[0007] An embodiment of the present invention will now be described in detail in conjunction with the accompanying drawings:

Fig.1 is a schematic cross sectional view of a single-split mould and a pneumatic tyre according to the present invention;

Fig.2 is a plan view of the tyre showing an example of the tread groove arrangement;

Fig.3 is an enlarged plan view showing the central circumferential groove and a main oblique groove thereof;

Fig.4 is a cross sectional view of the central circumferential groove;

Figs.5A, 5B and 5C are cross sectional views of the main oblique groove taken along lines I-I, II-II and III-III in Fig. 3, respectively;

Fig.6 is a sectional view taken along the centre line of the main oblique groove; and

Fig.7 is an enlarged cross sectional view of a secondary oblique groove.

[0008] In the drawings, a pneumatic tyre 1 according to the present invention comprises a tread portion 2, a pair of sidewall portions, a pair of bead portions each with a bead core therein (not shown) and a carcass (not shown) extending between the bead portions. The tread portion 2 is provided between tread edges Te with tread grooves G forming a tread pattern. The tread grooves G include at least one circumferential groove and a plurality of oblique grooves.

[0009] According to the present invention, the pneumatic tyre 1 is formed by a single-split mould 30 comprising a first piece 31U and a second piece 31L. As a result, a mould parting line (31) runs on or near the tyre equator C0. When opening the mould 30, the first piece 31U and second piece 31L move towards both sides of the tyre in parallel with the tyre axial direction. Incidentally, the inner face of the mould 30 is profiled and comprises a tread shaping face 32 with protrusions 35 for making the tread grooves G; a pair of sidewall-shaping faces 33, and a pair of bead shaping faces 34. In this example, the first piece 31U and second piece 31L are mounted on a ram and a bed of a press, respectively. Thus, the mould 30 can be opened and closed by up and down movements of the ram. The split face 31 between the two pieces 31U and 31L is positioned on the tyre equator C0 on the tread shaping face 32.

[0010] Fig.2 shows an example of the tread groove arrangement or the tread pattern, which, in this example, is a bi-directional tread pattern being substantially rotationally symmetrical. But, it is also possible to provide a uni-directional

tread pattern being substantially symmetrical about the tyre equator C. Usually, pitch variations are employed in arranging tread grooves such as oblique grooves around the tyre, and a circumferential phase shift is made between a right half tread pattern and a left half tread pattern. Accordingly, a strictly symmetrical pattern is rare. Thus the expression "substantially symmetrical" is meant to include such fluctuations.

[0011] Here, the above-mentioned tread edges Te mean the axial outermost edges of the ground contacting region under such a condition that the tyre is mounted on a standard rim and inflated to a standard pressure, and then loaded with a standard load. The standard rim is the "standard rim" specified in JATMA, the "Measuring Rim" in ETRTO, the "Design Rim" in TRA or the like. The standard pressure is the "maximum air pressure" in JATMA, the "Inflation Pressure" in ETRTO, the maximum pressure given in the "Tyre Load Limits at Various Cold Inflation Pressures" table in TRA or the like. In case of passenger car tyres, however, 180 kPa is used as the standard pressure. The standard load is the "maximum load capacity" in JATMA, the "Load Capacity" in ETRTO, the maximum value given in the above-mentioned table in TRA or the like.

[0012] The under-mentioned tread central portion 2C is defined as a portion centred on the tyre equator C and having a 50% width of the tread width TW. The remaining 25% width portion on each side of the central portion 2C is referred as shoulder portion 2S. The tread width TW is the axial width between the tread edges Te.

[0013] Because the demoulding defects are more liable to occur in the tread central portion 2C than the shoulder portions 2S, there are provided demoulding-defect preventing means mainly on tread grooves which are partially or wholly existing in the tread central portion 2C. However, if groove inclination with respect to the tyre circumferential direction is more than 45 degrees, such means are not necessary.

[0014] The demoulding-defect preventing means are provided as follows.

[0015] In the example shown in Fig.1, a central circumferential groove 9 and an axially outer circumferential groove 3 on each side thereof are provided. Further, as to the oblique grooves, main oblique grooves 4 and secondary oblique grooves 10, each extending axially inwardly from one of the outer circumferential grooves 3, are disposed.

[0016] The central circumferential groove 9 is a substantially straight groove extending continuously along the tyre equator C.

[0017] The axially outer circumferential grooves 3 are also substantially straight groove extending continuously around the tyre in parallel with the tyre equator C. Each outer circumferential groove 3 is disposed in a middle region which region is defined as extending towards each side from the border between the central portion 2C and shoulder portion 2S by 5% of the tread width TW. In this example, the circumferential groove 3 extends along the border line. In case of passenger car tyres, the width W0 of the outer circumferential groove 3 is at least 2.5 % preferably more than 3.0 % of the tread width TW.

[0018] The demoulding-defect preventing means are therefore, provided on the central circumferential groove 9 but not provided on the outer circumferential grooves 3.

[0019] The demoulding-defect preventing means in this case is a chamfer portion 21B accompanied by a recess 23. The chamfer portion 21B is provided on the groove edge which is stroked by the protrusions 35 of the mould 30 when the mould is opened. The recess 23 is formed near and axially outside the chamfer portion 21B.

[0020] In the case of the central circumferential groove 9, as the mould parting line runs in the groove bottom, the chamfer portion 21B and recess 23 are provided on each edge as shown in Figs.3 and 4. Therefore, each of the groove walls 21 comprises a main portion 21A extending radially outwardly from the groove bottom 22 and the chamfer portion 21B extending radially outwardly from the radially outer end of the main portion 21A to the tread face 2 with both inclining axially outwards. In a cross section normal to the groove centre line, the inclination of the groove wall 21 with respect to the normal direction to the tread face is as follows: the inclination angle $\delta 2$ of the main portion 21A is preferably set in a range of from 2 to 8 degrees; the inclination angle $\delta 1$ of the chamfer portion 21B is set in a range of from 30 to 60 degrees. The axial width L3 between the outer and inner ends P1 and P2 of the chamfer portion 21B is set in a range of from 0.3 to 2.0 mm. Further, the corner C1 between the main portion 21A and groove bottom 22 is rounded by a radius r1 of from 0.5 to 2.0 mm.

[0021] The recess 23 is formed on the tread face alongside the chamfer portion 21B. The recess 23 has a sectional shape having a curved base such as a semicircle, semi-oval and the like. In the cross section normal to the groove centre line, the width W4 of the recess 23 is in a range of from 0.3 to 3.0 mm when measured in parallel with the tread face, and the depth D4 thereof is in a range of from 0.3 to 2.0 mm when measured from the tread face to the deepest point. The distance L4 from the outer end P1 to the recess 23 is set in a range of from 0.5 to 2.0 mm.

[0022] As to the outer circumferential groove 3 in this example, as the axially outer groove wall is outside the tread central portion 2C, the chamfer portion 21B and recess 23 are not formed. Each of the axially outer and inner groove walls is composed of a main portion 21A extending from the groove bottom 22 to the tread face 2 while inclining outwards at the above-mentioned inclination angle $\delta 2$. If need be, however, it is possible to provide the chamfer portion 21B and recess 23 in the same manner as the central groove 9.

[0023] Owing to the chamfer portion 21B backed by the recess 23, demoulding defects can be effectively controlled although the size of the chamfer portion 21B and recess 23 and the distance therebetween are considerably small.

[0024] As to the above-mentioned main oblique grooves 4, each extends axially inwardly from one of the outer circumferential grooves 3, but, as shown in Fig.2, does not reach to the central circumferential groove 9 to form a circumferentially continuous rib on each side of the central circumferential groove 9.

[0025] Each main oblique groove 4 comprises an axially inner circumferential portion 4B and an axially outer inclined portion 4A. The inclined portion 4A extends axially inwardly from the outer circumferential groove 3. The inclination angle θ_1 thereof with respect to the tyre circumferential direction is set in a range from 30 to 60 degrees, preferably 40 to 50 degrees at the junction J1 with the circumferential groove 3. From the junction J1 towards the axially inside, the inclination angle θ_1 gradually decreases to substantially zero degrees so that the inclined portion 4A merges into the circumferential portion 4B. The circumferential portion 4B extends substantially parallel to the tyre circumferential direction. The distance L1 from the tyre equator C to the centre line of the circumferential portion 4B is set in a range of not more than 15 % of the tread width TW. The circumferential length L2 of the inclined portion 4A is set in a range of not less than 50 % of the total circumferential length L0 of the main oblique grooves 4.

[0026] As the main oblique grooves 4 each have a certain circumferential extent and a certain depth, demoulding-defect preventing means is provided. In this case, the means is a variable inclination α of the axially outer groove wall 4o. Figs.5A, 5B and 45C each show a cross section normal to the groove centre line. The inclination α becomes maximum (α_{max}) in the vicinity of the groove bent point K or connect point K of the inclined portion 4A and circumferential portion 4B (see Fig.3). To be exact the connect point K may be defined as the meeting of the centre line of the inclined portion 4A and the centre line of the circumferential portion 4B.

[0027] The maximum inclination α_{max} is set in the range of from 15 to 45 degrees, preferably 15 to 25 degrees.

[0028] This maximum inclination α_{max} continues for a certain length and then in subsequent portions YB and YC (hereinafter the "angularly changing portions YB and YC"), the inclination angle α gradually decreases towards the axially outer and inner ends of the groove.

[0029] Further, the corner 4c between the axially outer groove wall 4o and groove bottom 4b is rounded by a radius of curvature (r) of not less than 1.0 mm. Usually, the radius (r) is set to be not more than 3.0 mm.

[0030] On the other hand, the axially inner groove wall 4i has an inclination angle \square in a range of from 0 to 6 degrees and, unlike the axially outer groove wall 4o, it is substantially constant along the length of the oblique groove 4.

[0031] As a result of the above-mentioned variable inclination, the top width W of the main oblique groove 4 becomes increased towards the point K from each of the axially inner and outer ends.

[0032] In this example further, the bottom width is increased in a part 6A which extends from the contact point K towards the inclined portion 4A and circumferential portion 4B. Accordingly, the top width W is maximum in the part 6A, and the top width W gradually decreases in the subsequent transitional parts 6B and 6C. The axially inner transitional part 6C extends to the end of the circumferential portion 4B. The axially outer transitional part 6B extends to a position before the outer circumferential groove 3, and from this position a constant width part R extends to the junction J1.

[0033] It is preferable that the transitional parts 6B and 6C entirely overlap with the angularly changing portions YB and YC, respectively.

[0034] The maximum top width at the point K is preferably set in a range of from 60 to 100 % of the top width W0 of the circumferential groove 3. The top width W at the junction J1 is preferably set in a range of from 25 to 80 % usually 40 to 60 % of the top width W0.

[0035] The depth (d) of the main oblique groove 4 may be constant, but as shown in Fig.6, it is preferable to gradually decrease the depth (d) from the circumferential groove 3 towards the axially inside. The depth at the junction J1 is substantially equal to the depth D0 of the circumferential groove 3. In the circumferential portion 4B, the depth is set in a range of not more than 80 % of the depth D0. In the example shown in Fig.6, each of the inclined portion 4A and circumferential portion 4B has a constant depth part and a variable depth part.

[0036] In this example, further, the circumferentially adjacent circumferential portions 4B are connected with each other by connecting grooves 7. The connecting grooves 7 are narrower and shallower than these portions and have a width of from 0.5 to 3 mm and a depth of from 2 to 5 mm. Therefore, the circumferential portions 4B and these narrow connecting grooves 7 form a groove which extends continuously in the tyre circumferential direction while repeatedly changing the width and depth. Although the narrow connecting grooves 7 extends in parallel with the tyre equator, as the width and depth are limited as above, demoulding defects on the narrow connecting grooves 7 can be controlled.

[0037] Therefore, it can be said that such limitations are demoulding-defect preventing means.

[0038] The above-mentioned secondary oblique groove 10 extends axially inwards from the outer circumferential groove 3 in substantially parallel with the inclined portion 4A and terminates before the circumferential portion 4B. The secondary oblique groove 10 has, at the junction J2 with the circumferential groove 3, an inclination angle θ of from 30 to 60 degrees, preferably 40 to 50 degrees with respect to the circumferential direction. The inclination angle θ gradually decreases from the junction J2 towards the axially inside while describing substantially a part of a circle.

[0039] In this example, an axially inner part 10A of the secondary oblique groove 10 has an inclination angle θ of less than 45 degrees with respect to the circumferential direction. As the secondary oblique groove 10 is narrower than

Claims

1. A tyre comprising a tread portion (2) in which a mould parting line by a single-split mould runs on or near the tyre equator (CO) defining a right-hand part of the tread portion on one side of the mould parting line and a left-hand part on the other side, the tread portion provided in at least a central part (2C) with tread grooves (4) each having a right-hand groove wall and a left-hand groove wall, characterised in that in the right-hand part, the right-hand groove walls are at least partially provided with an inclined part (21B) extending from the tread face (2) towards the groove bottom (22) while inclining to the left, and the left-hand groove walls are inclined less than the inclined part (21B) of the respective opposite right-hand groove walls, in the left-hand part, the left-hand groove walls are at least partially provided with an inclined part (21B) extending from the tread face (2) towards the groove bottom (22) while inclining to the right, and the right-hand groove walls are inclined less than the inclined part of the

respective opposite left-hand groove walls, the inclined parts are a first inclined part extending from the tread face to the vicinity of the groove bottom, inclining at an first inclination angle of from 15 to 45 degrees, and/or a second inclined part inclined at a second inclination angle of from 30 to 60 degrees and having a width of from 0.3 to 2 mm when measured in parallel to the tread face and accompanied by a recess (23) which is narrower and shallower than the tread groove and extends along the second inclined part.

2. A tyre according to claim 1, characterised in that the tread grooves include a circumferential groove provided with the second inclined part accompanied by the recess.
3. A tyre according to claim 1 or 2, characterised in that the tread grooves include oblique grooves provided with the first inclined part.
4. A tyre according to claim 1, characterised in that the tread grooves include wide oblique grooves provided with the first inclined part, and narrow oblique grooves provided with the second inclined part accompanied by the recess.
5. A tyre according to claim 1, characterised in that the tread grooves include a circumferential groove provided with the second inclined part accompanied by a recess, wide oblique grooves provided with the first inclined part, and narrow oblique grooves provided with the second inclined part accompanied by a recess.
6. A tyre according to claim 3, 4 or 5, characterised in that each of the oblique grooves extends axially inwardly from an axially outer circumferential groove, the axially outer circumferential groove is disposed on each side of the tyre equator and not provided with the inclined part.
7. A tyre according to claim 5, characterised in that each of the wide oblique grooves comprises an axially inner circumferential portion and an axially outer inclined portion which merges into the axially inner circumferential portion, an inclination angle of the axially outer inclined portion with respect to the tyre circumferential direction gradually decreases from an angle at the axially outer end thereof which is in a range of from 30 to 60 degrees to substantially zero degrees at a connecting point with the circumferential portion, and the first inclination angle of the first inclined part has a maximum in the vicinity of the connecting point and gradually decreases towards both side thereof, whereby the groove width at the groove top becomes wider in the vicinity of the connecting point.
8. A tyre according to claim 7, characterised in that the groove width at the groove bottom is increased in the vicinity of the connecting point.
9. A tyre according to claim 7, characterised in that the depth of each of the wide oblique grooves gradually decreases from the axially outer end to the axially inner end thereof.
10. A tyre according to claim 7, characterised in that the circumferentially adjacent circumferential portions are connected with each other by circumferentially extending narrow connecting grooves having a width of from 0.5 to 3 mm and a depth of from 2 to 5 mm.
11. A tyre according to claim 2, characterised in that the circumferential groove is disposed on the mould parting line and both the groove walls thereof are provided with the second inclined part accompanied with a recess, whereby the recess is formed on each side of the circumferential groove.
12. A tyre according to any of claims 1 to 11, characterised in that the recess has a width of from 0.3 to 3 mm and a depth of from 0.3 to 2.0 mm.
13. A tyre according to any of claims 1 to 12, characterised in that the corner between the groove wall provided with the inclined part and the groove bottom is rounded.
